

# PhD Lecture in Behavioral Asset Pricing: Introduction

Frank Weikai Li

Associate Professor of Finance  
City University of Hong Kong

- **Definition 1:**

- Behavioural Finance investigates whether some financial phenomena are the result of less than fully rational thinking

- **Three paradigms in finance:**

- Traditional finance
  - Agents are rational and there are no frictions
- Frictional finance
  - Agents are rational but there are frictions
- Behavioral finance
  - Some agents are less than fully rational

- **Rationality means two things:**

- Update beliefs correctly on receipt of new information, i.e. according to Bayes' rule
- Make decisions according to sensible preferences, i.e. according to expected utility
  - Where the utility function is defined over wealth or consumption

- **In behavioural finance, then:**

- We study less than fully rational beliefs
  - Deviations from Bayes' rule
- And less than fully rational preferences
  - Non-EU, or EU defined over things other than wealth or consumption

- **Definition 2:**

- Behavioral finance tries to understand financial phenomena using models that are *psychologically more realistic* than their predecessors

- **Three paradigms in finance:**

- **Traditional finance**

- Very basic, psychologically and institutionally

- **Frictional finance**

- More realistic, institutionally

- **Behavioral finance**

- More realistic, psychologically
  - More psychologically realistic assumptions about beliefs
  - More psychologically realistic assumptions about preferences

# Challenges for Behavioural Finance

- **The arbitrage critique**

- Claim: rational agents will quickly undo any effect irrational agents have on prices
  - They will engage in “arbitrage”
- We now know that there are “limits to arbitrage”

- **The lack-of-discipline critique**

- Claim: behavioural finance is “underdisciplined”; it is too easy to find psychology that fits the facts
  - Address this by testing new predictions

- **I. Introduction**

- Overview
- Facts
  - Asset price
  - Investor trading and portfolio choice

- **II. Limits to Arbitrage**

- **III. Psychological Foundation and Applications in Finance**

- Non-standard preferences
- Biased beliefs
- Heterogeneous beliefs
- Bounded rationality and psychology-free models

- **Asset pricing**

- Aggregate stock market
- Cross-section of stock returns
- Other asset classes
- Bubbles

- **Investor trading and portfolio choice**

- Individual investors
- Institutional investors

# Aggregate Stock Market, ctd.

- **The time-series predictability puzzle**

- Aggregate stock market returns are predictable in the time series
  - E.g. by the price-dividend (P/D) or price-earnings ratio (P/E)
- This seems to contradict efficient market hypothesis

## Aggregate stock market, ctd.

- *The time-series predictability puzzle*

- Aggregate stock market returns are predictable in the time series
  - E.g. by the price-dividend (P/D) or price-earnings ratio (P/E)
- This seems to contradict efficient market hypothesis

Subsequent 10-year returns on S&P500

### Rational explanations?

- Rationally-changing forecasts of future risk – “rare disaster” and long-run risk model
- Time-varying risk aversion like the habit formation model (Campbell and Cochrane, 1999)

## Rational explanations?

Rationally-changing forecasts of future risk — “rare disaster” and long-run risk model

Time-varying risk aversion like the habit formation model (Campbell and Cochrane, 1999)

# Aggregate Stock Market, ctd.

- **The excess volatility puzzle**

- It is hard to justify stock market fluctuations on the basis of rationally-varying forecasts of the future cash flows paid to investors (Shiller 1981)
- High P/D ratio does not predict higher dividend growth, instead it predicts lower price in future
- Time-series predictability and excess volatility are the same phenomenon

FIGURE 1

*Note:* Real Standard and Poor's Composite Stock Price Index (solid line  $p$ ) and *ex post* rational price (dotted line  $p^*$ ), 1871–1979, both detrended by dividing a long-run exponential growth factor. The variable  $p^*$  is the present value of actual subsequent real detrended dividends, subject to an assumption about the present value in 1979 of dividends thereafter. Data are from Data Set 1, Appendix.

- **The equity premium puzzle**

- The historical equity premium (5%) is much higher than predicted by a simple rational, frictionless model with power utility preferences (Mehra and Prescott, 1985)
- The covariance of stock market returns with consumption growth is small
- The representative investor does not view the stock market as very risky, and requires a very low equity premium

# The Cross-Section of Stock Returns

# The Cross-Section, ctd.

- **Long-term reversal**

- A stock's cumulative return over the past 3–5 years negatively predicts its future return in the cross-section (De Bondt and Thaler, 1985)
- Rational hypothesis?
- What are other patterns that you notice?

# The Cross-Section, ctd.

## • Momentum

- A stock's  $k$ -month past return ( $k$  between 3 and 12) positively predicts its future returns in the cross-section (Jegadeesh and Titman, 1993)
- Explaining both momentum and long-term reversal in a unified and parsimonious framework is an important challenge

### The cross-section, ctd.

#### • Momentum

- A stock's  $k$ -month past return ( $k$  between 3 and 12) positively predicts its future returns in the cross-section (Jegadeesh and Titman, 1993)
- Explaining both momentum and long-term reversal in a unified and parsimonious framework is an important challenge

13

# The Cross-Section, ctd.

## • Short-term reversal

- A stock's return over the past week or month negatively predicts its future return in the cross-section (Jegadeesh, 1990; Lehmann, 1990)
- Could be explained by compensation for liquidity provision
- The returns of short-term reversal strategies in equity markets is highly predictable with the VIX index (Nagel, 2012)

Figure 1

Three-month moving averages of daily return-reversal strategy returns and the CBOE S&P 500 implied volatility index (VIX)

Each day  $t$ , the reversal strategy returns are calculated as the average of returns from five reversal strategies that weight stocks proportional to the negative of market-adjusted returns on days  $t-1$ ,  $t-2$ , ...,  $t-5$ , with weights scaled to add up to \$1 short and \$1 long. Returns are calculated from daily CRSP closing transaction prices, and returns are hedged against conditional market factor exposure.

Nagel (RFS 2012)

# The Cross-Section, ctd.

- **The value premium**

- Ratios of fundamentals to price (B/M, E/P, CF/P) positively predict future returns

## The cross-section, ctd.

- *The value premium*

- Ratios of fundamentals to price (B/M, E/P, CF/P) positively predict future returns

# The Cross-Section, ctd.

- The value and momentum effects also exist in other asset classes (Asness, Moskowitz, and Pedersen, 2013)
  - Within most developed equity markets, across country equity indices, across government bond indices, across currencies, and across commodities

# The Cross-Section, ctd.

- **The issuance/repurchase anomaly**

- Firms that issue equity (IPO or SEO) subsequently do poorly, relative to a control group (Loughran and Ritter, 1995)
- Firms that repurchase equity subsequently do well, relative to a control group (Ikenberry, Lakonishok, and Vermaelen, 1995)

# The Cross-Section, ctd.

- **The asset growth / investment anomaly**

- Firms that grow assets more quickly or invest more have lower risk-adjusted return (Titman, Wei, and Xie, 2004; Cooper, Gulen, and Schill, 2008)

# The Cross-Section, ctd.

- **The Profitability anomaly:** more profitable firms (quintile 5) earn higher returns than less profitable firms (quintile 1)
- Profitability is related to a broad set of *Quality* characteristics
  - Asness, Frazzini, & Pedersen (2019) suggest a multiple dimensional gauge of quality: profitability, recent growth in profits, low return and earnings volatility, and low leverage

## The cross-section, ctd.

- *The Profitability anomaly:* more profitable firms (quintile 5) earn higher returns than less profitable firms (quintile 1)
- Profitability is related to a broad set of Quality characteristics
  - Asness, Frazzini, & Pedersen (2018) suggest a multiple dimensional gauge of quality. [Profitability, recent growth in profits, low return and earnings volatility, low credit risk, high dividend yields.]

# The Cross-Section, ctd.

- **The financial distress anomaly**

- Financially distressed stocks earn lower alphas (Campbell, Hilscher, and Szilagyi, 2008)

**Figure 2. Alphas of distressed stock portfolios.** The figure plots the annualized mean excess return over the market, CAPM alpha, and Fama–French three-factor alpha for the 10 distress risk-sorted portfolios from 1981 to 2003. Portfolios are formed at the beginning of January every year using the model-predicted probability of failure.

# The Cross-Section, ctd.

- **Post-earnings announcement drift**

- The surprise in a firm's most recent earnings announcement positively predicts future returns

- **Other related findings:**

- The revision in analysts' consensus earnings forecast/recommendations positively predicts future returns

**Figure 11.5** Cumulative abnormal returns in response to earnings announcements

Source: Reprinted from R. J. Rendleman Jr., C. P. Jones, and H. A. Latané, "Empirical Anomalies Based on Unexpected Earnings and the Importance of Risk Adjustments," *Journal of Financial Economics* 10 (1982), pp. 269–287.

# The Cross-Section, ctd.

- **Idiosyncratic volatility puzzle**

- Stocks with higher idiosyncratic volatility have lower alphas (Ang et al., 2006)

Baker, Bradley and Wurgler (2011, FAJ)

## • The Beta Anomaly

- Stocks with higher betas have similar raw return and lower CAPM alpha than low beta stocks
- In other words, the empirical SML is too flat compared to that predicted by CAPM

Figure 2

Average Annualized Monthly Return versus Beta for Value Weight Portfolios Formed on Prior Beta, 1928–2003

Fama and French (2004)

# The Cross-Section, ctd.

- Similar findings in other countries and other asset classes (Frazzini and Pedersen, 2014)
- **Betting against beta** is highly profitable

# The Cross-Section, ctd.

## Firm-level characteristics with predictive power for stock returns in the cross-section

| Characteristic              |   |
|-----------------------------|---|
| Past three-year return      | - |
| Past six-month return       | + |
| Past one-month return       | - |
| Earning surprise            | + |
| Market capitalization       | - |
| Price-to-fundamentals ratio | - |
| Issuance                    | - |
| Systematic volatility       | - |
| Idiosyncratic volatility    | - |
| Profitability               | + |

- Situations where, for a significant period of time, an asset trades at a price that appears to be substantially higher than its rational/frictionless price
- Bubbles appear to exhibit following characteristics:
  - (i) The price of an asset rises sharply over some period of time and then declines, reversing much of the rise
  - (ii) During the price rise, there are many reports in the media and from sophisticated investors that the asset is overvalued
  - (iii) As the price of the asset rises and reaches its peak, there is an abnormally high volume of trading in the asset
  - (iv) During the episode, many investors have highly extrapolative expectations about returns, in that their expectation about the asset's future return rises with the asset's past return
  - (v) During the price rise, some sophisticated investors increase their exposure to the asset
  - (vi) In the early stages of the price rise, there is positive news about the asset's future fundamental

# Famous Bubbles in History

As of 1/9/2021. Source: Elliot Wave Int., Yale SOM, St. Louis FRED, Coindesk, Global Financial Data.

# Bubbles, ctd.

- Bubbles tend to be accompanied by very high trading volume (Hong and Stein, 2007)
- And sophisticated traders often “ride” the bubble (Brunnermeier and Nagel, 2004)
- Understanding bubbles is an important challenge
  - Their collapse can trigger severe economic downturns

Figure 1: Prices and Turnover for Internet and Non-Internet Stocks, 1997-2002

- **Individual investors**

- Non-participation
- Buying high and selling low
- Under-diversification
- Excessive trading
- Sell winners too quickly and hold on to losers for too long (“Disposition effect”)

- **Institutional investors**

- Average performance
- Trade against anomalies
- Sentiment-driven trading

- **Non-participation**

- Historically, most U.S. households held no stock at all
  - E.g. in 1984, only 28% of households held any stock (Mankiw and Zeldes, 1991)
- But a simple rational, frictionless model of portfolio choice predicts that all households should have at least some stock market exposure

- **Rational hypotheses?**

- Fixed transaction costs in participating in stock market
- Correlated background risk including labor income and real estate

# Individual Investors, ctd.

- **Buying high, selling low**

- Investors' actual historical returns are much lower than the buy-and-hold returns (Dichev, 2007)

## Individual Investors, ctd.

*Buying high, selling low*

- Investors' actual historical returns are much lower than the buy-and-hold returns (Dichev, 2007)

TABLE 5—RETURN RESULTS FOR 19 MAJOR INTERNATIONAL STOCK EXCHANGES

| Country        | Buy-and-hold<br>return              | Dollar-weighted<br>return | Difference<br>(BH Ret – DW Ret) | P-value for<br>difference |

| Equal-weighted | Average difference<br>(t-statistic) |                           | 0.015<br>(5.25)                 |                           |
| Value-weighted | Average difference<br>(t-statistic) |                           | 0.014<br>(45.98)                |                           |

# Individual Investors, ctd.

- Many households seem to be less diversified than recommended by traditional models of portfolio choice
- **Under-diversification: Home bias**
  - Investors allocate a surprisingly large fraction of their equity holdings to domestic equity
  - In 1989, U.S., U.K., and Japanese households invested 94%, 82% and 98% of their equity holdings in domestic equity (French and Poterba, 1991)
- **Under-diversification: Local bias**
  - The typical U.S. household has about 30% of its portfolio invested in stocks headquartered within a 250-mile radius of the family's home
- **Rational explanations?**
  - Information advantage in local firms
  - Mixed evidence for this explanation (Ivkovic and Weisbenner, 2005; Seasholes and Zhu, 2010)

# Individual Investors, ctd.

- **Under-diversification: Ownership of few individual stocks**

- Curcuru et al. (2004) report that, in 1989, 30% of U.S. equity-owning households allocated more than 50% of their equity exposure to fewer than 10 stocks

- **Under-diversification: Own-company stock**

- Benartzi (2001) reports that, in a sample of 154 retirement plans, people allocated 23% of their discretionary contributions to own-company stock

## Stocking Up

A sample of retirement plans in which the company's own stock is a large share of the total assets

| Company             | Retirement plan                            | Company stock as a share of total assets |
|---------------------|--------------------------------------------|------------------------------------------|
| Sherwin-Williams    | Employee Stock Purchase and Savings Plan   | 65.2%                                    |
| Scana               | 401(k) Savings Plan                        | 64.9                                     |
| Colgate-Palmolive   | Employees Savings & Investment Plan        | 60.7                                     |
| Lowe's              | 401(k) Plan                                | 56.4                                     |
| Exxon Mobil         | Savings Plan                               | 54.3                                     |
| Kroger              | Savings Plan                               | 52.9                                     |
| Dillard's           | Investment & Employee Stock Ownership Plan | 50.6                                     |
| Cerner              | Foundations Retirement Plan                | 46.9                                     |
| Paccar              | Savings Investment Plan                    | 44.4                                     |
| Abbott Laboratories | Stock Retirement Plan                      | 42.6                                     |
| Costco              | 401(k) Retirement Plan                     | 41.7                                     |
| Chevron             | Employee Savings Investment Plan           | 41.4                                     |
| Phillips 66         | Savings Plan                               | 40.9                                     |
| McDonald's          | Profit Sharing and Savings Plan            | 40.5                                     |
| General Electric    | Retirement Savings Plan                    | 38.6                                     |

Note: Companies may offer retirement plans other than those shown here. Data are for companies with at least \$1 billion in net assets as of Dec. 31, 2015.

- **Excessive trading**

- Using data on 66,465 households with accounts at a large discount brokerage firm, Barber and Odean (2000) find that investors who trade more earn lower return in stock market

- **Disposition effect**

- Individual investors have a greater tendency to sell stocks trading at a gain relative to purchase price, rather than at a loss (Odean, 1998)
- Tested by Odean (1998) using the following hypothesis on investor behavior:
- Proportion of Gains Realized (PGR) > Proportion of Losses Realized (PLR)

### PGR and PLR for the Entire Data Set

This table compares the aggregate Proportion of Gains Realized (PGR) to the aggregate Proportion of Losses Realized (PLR), where PGR is the number of realized gains divided by the number of realized gains plus the number of paper (unrealized) gains, and PLR is the number of realized losses divided by the number of realized losses plus the number of paper (unrealized) losses. Realized gains, paper gains, losses, and paper losses are aggregated over time (1987–1993) and across all accounts in the data set. PGR and PLR are reported for the entire year, for December only, and for January through November. For the entire year there are 13,883 realized gains, 79,658 paper gains, 11,930 realized losses, and 110,348 paper losses. For December there are 866 realized gains, 7,131 paper gains, 1,555 realized losses, and 10,604 paper losses. The *t*-statistics test the null hypotheses that the differences in proportions are equal to zero assuming that all realized gains, paper gains, realized losses, and paper losses result from independent decisions.

|                           | Entire Year | December | Jan.–Nov. |
|---------------------------|-------------|----------|-----------|
| PLR                       | 0.098       | 0.128    | 0.094     |
| PGR                       | 0.148       | 0.108    | 0.152     |
| Difference in proportions | −0.050      | 0.020    | −0.058    |
| <i>t</i> -statistic       | −35         | 4.3      | −38       |

- A similar effect is present among mutual fund managers (Frazzini, 2006) and also in the housing market (Genesove and Mayer, 2001)
- The most obvious potential explanations, e.g. informed trading, fail to capture important features of the data
  - Subsequent return of winners that people sell is higher than that of losers they hold on to
- The disposition effect is more pronounced among less sophisticated investors (Dhar and Zhu, 2006)

- **Trading against anomalies—forecast returns**
- Firms and short sellers tend to be the smart money—both sell stocks with **low-forecasted returns**

McLean, Pontiff and Reilly (JFE 2025)

- **Average performance**

- A basic frictionless model with skilled managers and rational investors (Berk and Green, 2004) predicts that:
  - Managers' gross alpha will be positive, on average
  - And their net alpha will be zero, on average
- In practice, the gross alpha of mutual funds appears to be positive, but not substantially so
- Does this suggest there is no mispricing?
  - No one earns abnormal profit equivalent to price is correct?

- **Trading against anomalies**

- Lewellen (2011) finds that institutional investors in aggregate essentially hold the market portfolio, with no discernible tilt to take advantage of well-known stock return anomalies
- Edelen, Ince and Kadlec (2016) find more striking result that institutions have a strong tendency to buy overvalued stocks during portfolio formation
- Hedge funds and institutions with high turnover seem to exploit anomalies more than other institutions

## Institutional Investors, ctd.

**Table 4**

Changes in institutional investor base for anomaly stocks.

The table presents annualized changes in institutional ownership during the anomaly portfolio formation period, 1982–2012. [See Fig. 1 for timeline and Table 1 for anomaly acronyms.]  $\Delta\#Inst$  is the change in the number of institutional investors scaled by the average number of institutions holding stocks in the same market capitalization decile at the beginning of the period.  $\Delta\%Inst$  is the change in fraction of shares held. +, +, +, and + indicate p-values of 1%, 5%, 10% or less, respectively. The p-values are estimated nonparametrically and adjusted for autocorrelation using moving block bootstrapping.

|     |       | $\Delta\#Inst$ | $\Delta\%Inst$ |     |       | $\Delta\#Inst$ | $\Delta\%Inst$ |
